Relationship Of Stump Diameter To D.b.h.

For Sugar Maple In The Northeast

This is the second report on a series of studies (2) made to show the relationship of stump diameter to diameter breast high (d.b.h.) for commercially important tree species in the Northeast. This report is for sugar maple (Acer saccharum).

In this study 1,021 stump-diameter measurements were used, ranging from 4 inches to 45 inches. Both stump diameters and d.b.h. were measured to the nearest 1/10 inch with a diameter tape. Bark thickness was measured with a Swedish bark gage. Stump heights were measured on the uphill side to the nearest 1/10 foot.

It was found that 72 percent of the stumps left on logging operations were between 0.6 and 1.8 feet high; 23 percent were higher than 1.8 feet; and only 5 percent were lower than 0.6 foot. Butt rot--rather than under-utilization--accounted for 22 percent of the stumps cut over 1.8 feet high.

In the computations, inside-bark stump diameters were used, to avoid inaccuracies due to unequal bark thickness, logging damage to bark, and bark peeling off. Stump diameters were sorted into 2-inch classes. Stump height measurements were sorted into 0.6-foot classes within each stump-diameter class.

To develop an equation expressing the stump diameter-d.b.h. relationship for sugar maple, the method described by Deming (1) was used. The following equation was obtained:

$$\text{D.b.h.} = 0.910 (\text{stump d.i.b.}) + 1.609 (\text{stump height}) - 2.271$$

The relationships developed from this equation were worked out as a graph (fig. 1).

By using the graph, the 2-inch d.b.h. class of a sugar maple stump can be found quickly. This is done by plotting the intersection of the vertical ordinate (stump height) with the horizontal ordinate (stump diameter). For example, for a stump 24.7 inches in diameter and 1.2 feet high, the two lines intersect about halfway between the two limits of the 22-inch d.b.h. class.

Comparison of actual d.b.h.'s and those calculated with the equation showed an average weighted difference of only 0.06 inch. The standard error of estimate for all data was only 0.9 inch. At the mean of stump diameters, you can expect 71 percent of the estimates of d.b.h. to fall in the correct 2-inch d.b.h. class. Another 26 percent can be expected to fall one class above or below the correct one; and 3 percent will fall outside this range. These errors are compensating. As the stump diameters increase beyond the mean of these data, the error will also increase.

(If you use the graph by 1-inch d.b.h. classes, this is what you can expect: 41 percent of the estimates should fall in the correct 1-inch d.b.h. class; 48 percent should fall one class above or below it; and 11 percent should fall outside this range.)

For all practical purposes, the graph is expected to give reliable d.b.h. estimates for sugar maple anywhere in the Northeast.
